## SULFONAMIDES

## QUINOLONE ANTIMICROBIALS

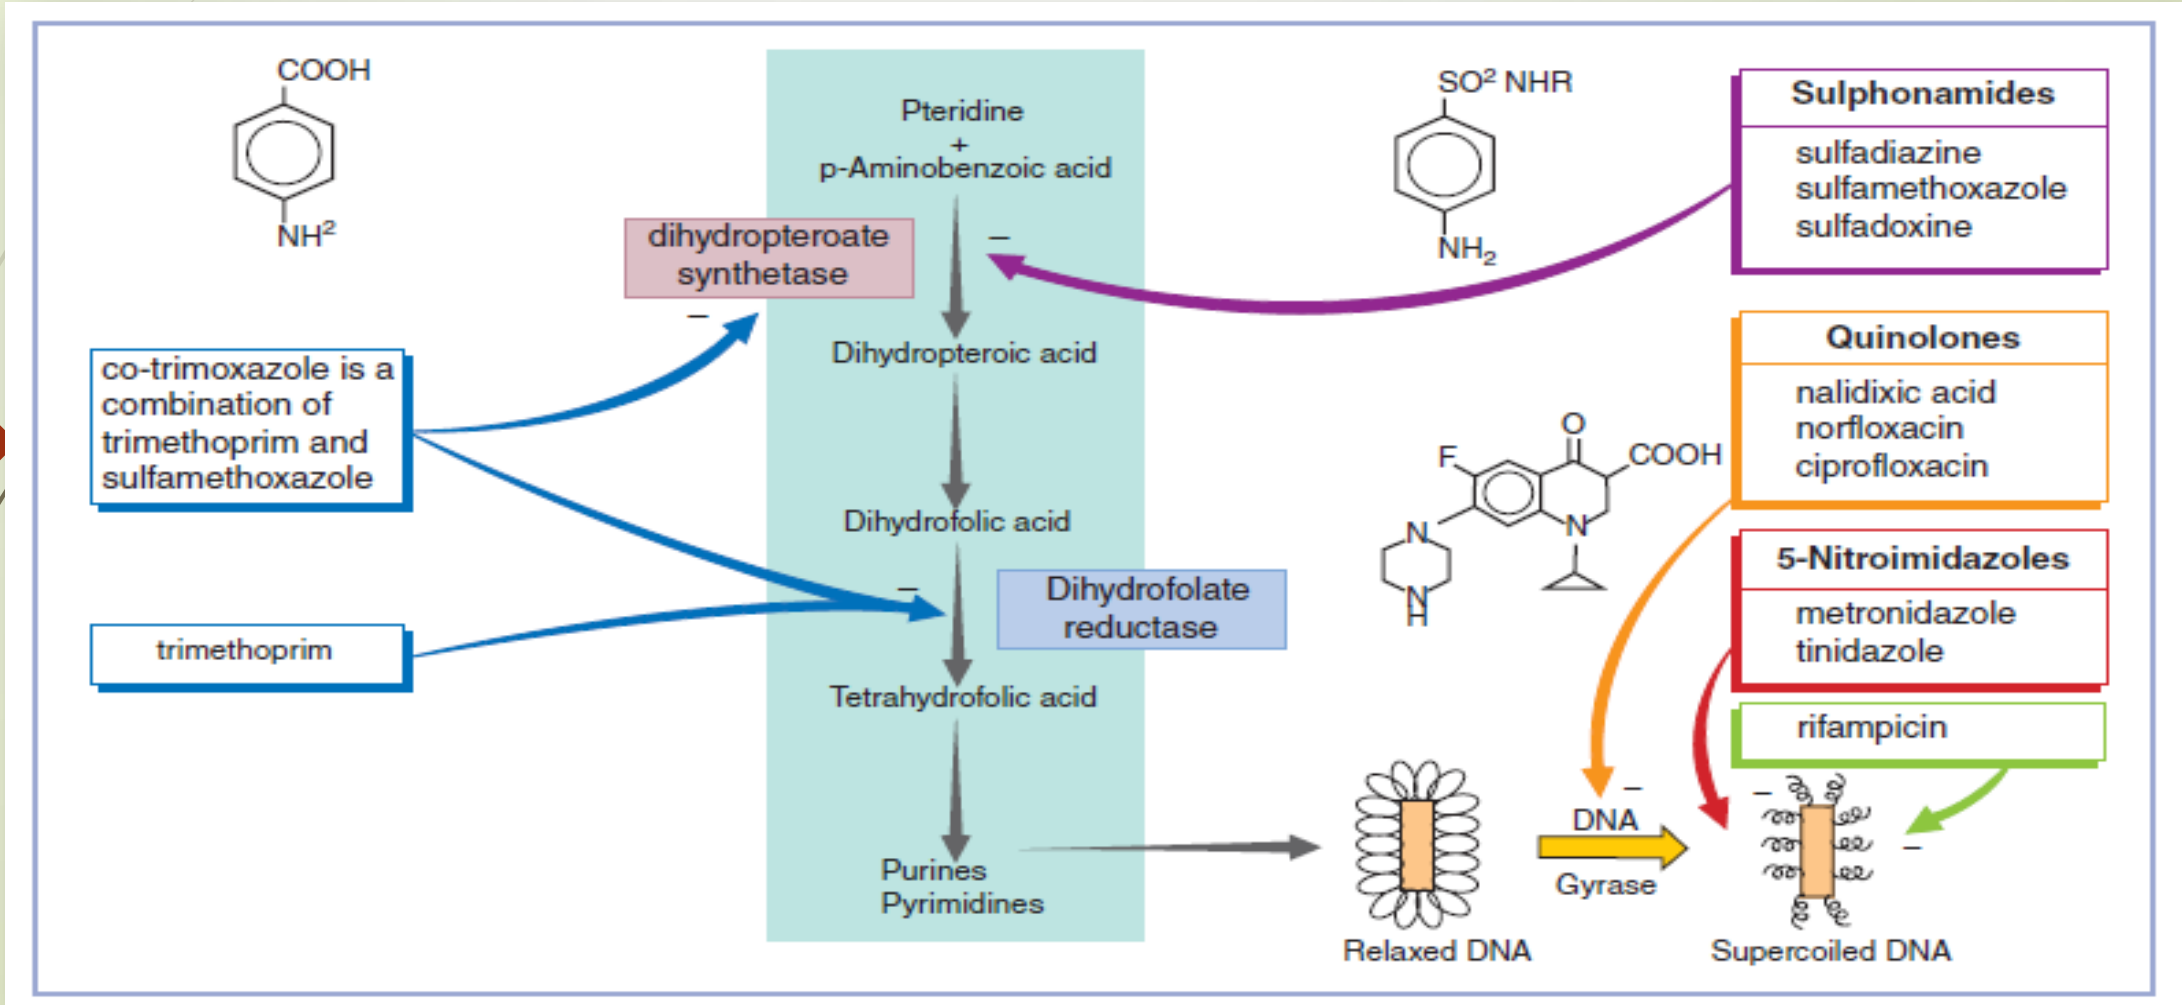

# MOA of Sulfonamide

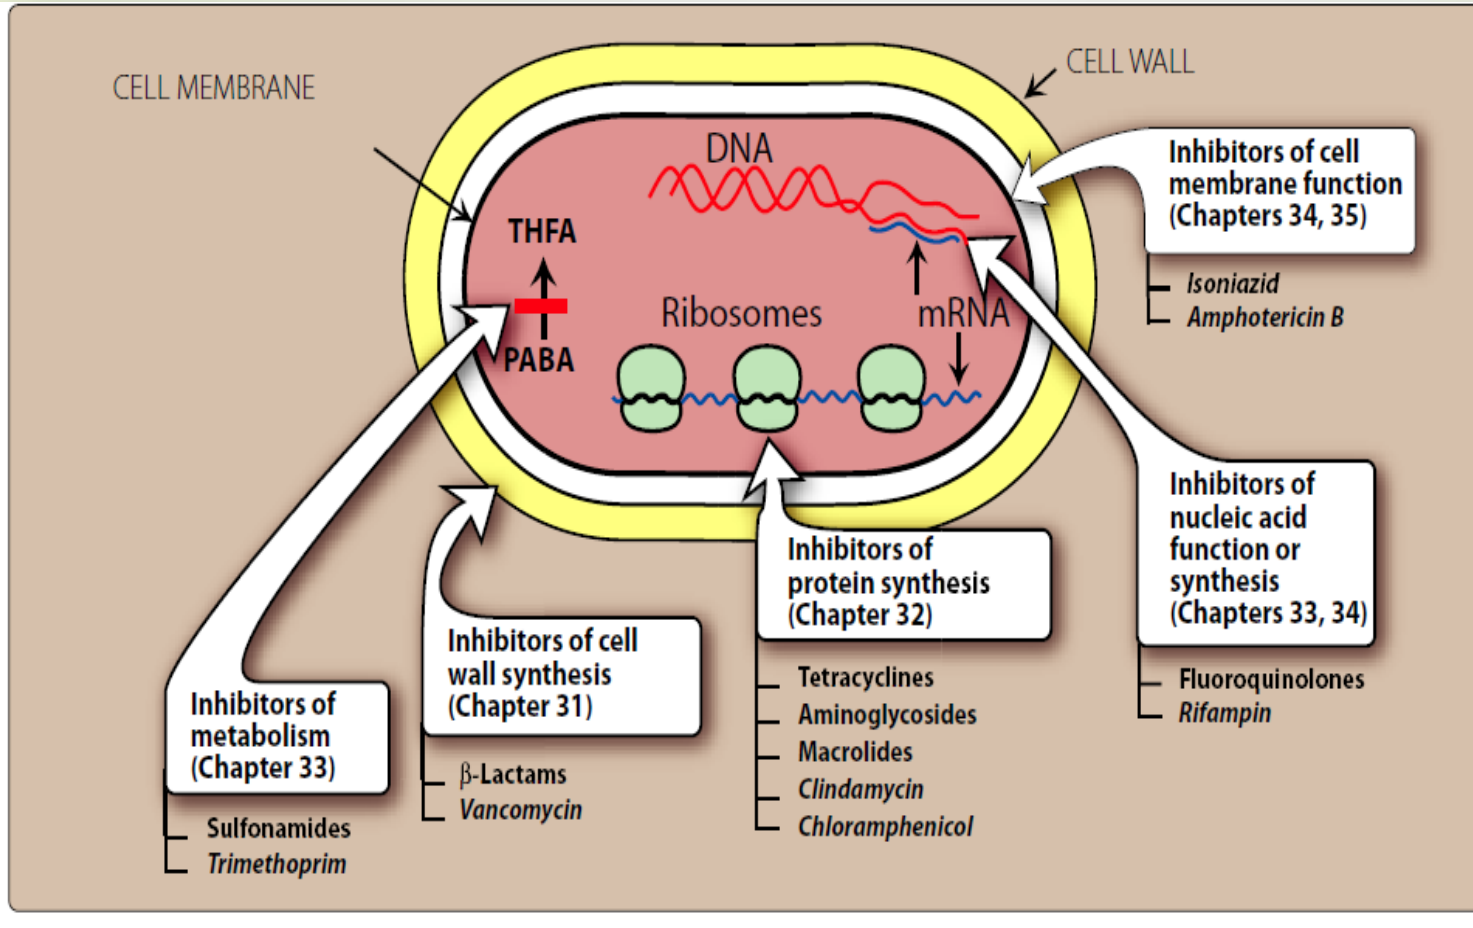

**FIGURE 46-1** Inhibitory effects of sulfonamides and trimethoprim on folic acid synthesis. Inhibition of 2 successive steps in the formation of tetrahydrofolic acid constitutes sequential blockade and results in antibacterial synergy.

- Bacteria synthesize their own folic acid (FA) from p-aminobenzoic acid (PABA)
- Structural analogues of PABA, inhibit bacterial folate synthesis → FA
- Sulfonamides are bacteriostatic inhibitors of folic acid synthesis.
- Antimetabolites of PABA, they are competitive inhibitors of dihydropteroate synthase
- Sulfonamides competitively inhibit the union of PABA with pteridine residue to form dihydropteroic acid
- Human cells also require FA, but they utilize preformed FA (ready made)
- Pus and tissue extracts antagonize sulfonamide as pus rich in thymidine, purine and PABA

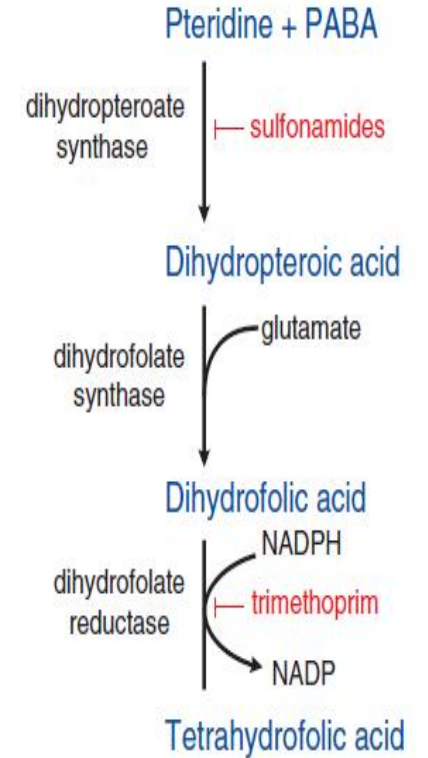

# MOA of Sulfonamide

**Figure 30.13**

Classification of some antimicrobial agents by their sites of action. (THFA = tetrahydrofolic acid; PABA = *p*-aminobenzoic acid.)

**Figure 56-2** Steps in folate metabolism blocked by sulfonamides and trimethoprim. Coadministration of a sulfonamide and trimethoprim introduces sequential blocks in the biosynthetic pathway for tetrahydrofolate; the combination is much more effective than either agent alone.

## Antibacterial spectrum of sulfonamides

### Sensitive microbes

- Strepto. pyogenes, Haemophilus influenzae, H. ducreyi, Calymmatobacterium granulomatis, Vibrio cholerae

- ➔ E.g. gonococci, pneumococci, Staph. aureus, meningococci, E. coli, Shigella and some Strep. pyogenes, Strep. viridans and anaerobes.

# Resistance is develop due to

**Decreased**  
intracellular  
accumulation  
of the drugs

increased  
amounts of  
PABA

**Low affinity** for  
folate  
synthase  
enzyme

pathway**  
developed by  
organisms

- **Resistance is develop due to**
  - **Decreased intracellular accumulation of the drugs**
  - **Increased production of PABA by bacteria**
  - **Low affinity for folate synthase enzyme**
  - **Adopt an alternative pathway in folate metabolism.**

# Drug resistance

- Resistance developed **in vivo** is quite persistent.
- **Sensitivity reduces** after long use

- **No cross resistance with other AMA**
- **Resistance limited** the clinical usefulness

# Pharmacokinetics

## ➤ Absorption:

- rapidly and nearly completely absorbed from g.i.t. exception is sulfasalazine

## ➤ Distribution

- cross placenta freely

# Pharmacokinetics..

## ➤ Metabolism

- Acetylation by microsomal acetyl transferase at N<sub>4</sub> in Liver
- Acetylated derivative is inactive,
- Less soluble in acidic urine, may precipitate and cause crystalluria

## ➤ Excretion

- eliminated by glomerular filtration
- require dose adjustments for renal dysfunction
- may also be eliminated in breast milk.

# Cotrimoxazole

**FIGURE 46-1** Inhibitory effects of sulfonamides and trimethoprim on folic acid synthesis. Inhibition of 2 successive steps in the formation of tetrahydrofolic acid constitutes sequential blockade and results in antibacterial synergy.

- Trimethoprim is diaminopyrimidine related to pyrimethamine (antimalarial)
- Trimethoprim a potent inhibitor of bacterial dihydrofolate reductase (DHFRase)
- Have **same** antibacterial spectrum to that of the sulfonamides.
- Trimethoprim is most often **combined with sulfamethoxazole**, producing the combination called cotrimoxazole (**fixed dose combination**)

### The bacterial chromosome

### Folate metabolism

Bacteriostatic antibacterial agent consisting of sulfamethoxazole + trimethoprim

**Co-trimoxazole**

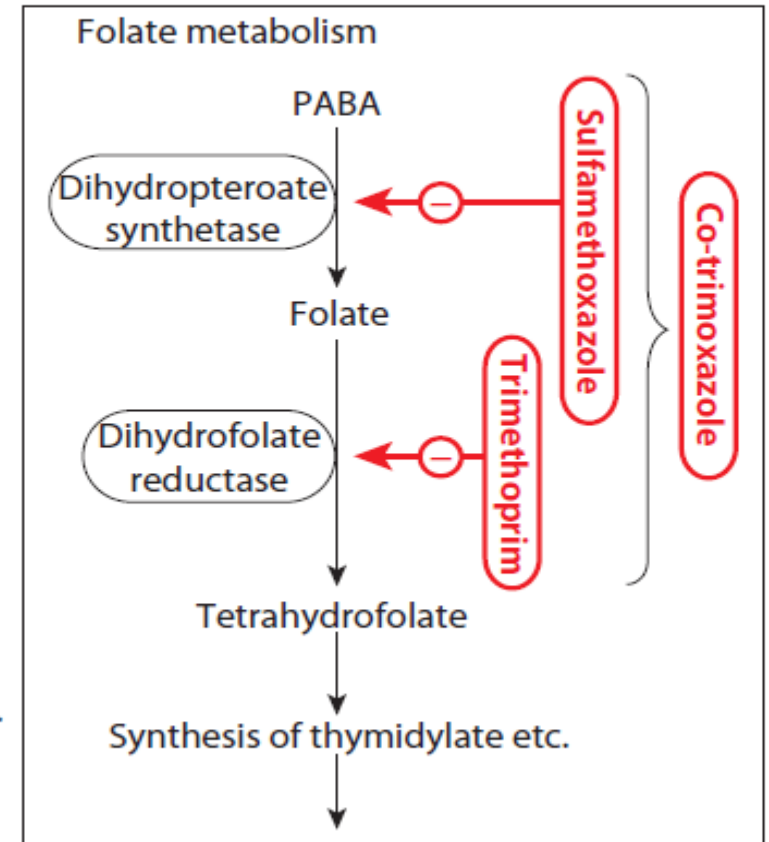

**Actions** Both sulfamethoxazole and trimethoprim interfere with bacterial folate metabolism and thus with DNA synthesis.

**MOA** Sulfamethoxazole competitively inhibits the enzyme dihydropteroate synthetase. Trimethoprim inhibits dihydrofolate reductase and thus the conversion of folate to tetrahydrofolate.

**Abs/Distrb/Elim** Given orally or by i.v. infusion. Sulfa drugs pass into inflammatory exudates, but are inactive in the presence of pus.

**Clinical use** Pneumocystis pneumonia, toxoplasmosis and nocardiasis, urinary infections, acute exacerbations of chronic bronchitis. Trimethoprim alone used for prostatitis, and for urinary and respiratory infections .

**Adverse effects** GIT upsets, rashes. Very rare but serious: Stevens-Johnson syndrome, blood dyscrasias, toxic epidermal necrolysis, photosensitivity.

# Cotrimoxazole

- **TMP >50,000 times more active** against bacterial DHFRase than mammalian
- Human folate metabolism is **not interfered**
- Individually, both are **bacteriostatic**
- In **combination** becomes **cidal** against organisms
- In sensitive microorganism **Maximum synergism** is observed

## Why Combination Preferred?

- ➔ **Maximum synergism**
- ➔ **Optimal synergy at a concentration ratio of SMZ  
20 : TMP 1 in Plasma**
- ➔ **Nearly the same  $t_{1/2}$  (~ 10 hr).**
- ➔ **MIC of each component reduced by 3–6 times.**
- ➔ **Dose ratio in the combination in tablets is 5 : 1  
(400 mg SMZ & 80 mg TMP)**

- ➔ **TMP enters many tissues, has a larger volume of distribution than SMZ**
- ➔ **TMP adequately crosses BBB but poor sulfamethoxazole**
- ➔ **TMP more rapidly absorbed than SMZ**
- ➔ **TMP 40% plasma protein bound, while SMZ is 65% bound.**
- ➔ **TMP Metabolized in liver and excreted in urine.**
